# Biochemical parameters-wise hypertension in an Indian community 

Maharaj Biswas*, Chanchal Kumar Manna<br>Endocrinology laboratory, Department of Zoology, Faculty of science, University of Kalyani, Kalyani-741235, Nadia, West Bengal, India

#### Abstract

Background: Now-a-days, hypertension is a most common cardiovascular disease and it accounts for large proportion of all cardiovascular deaths and disabilities worldwide. The main aim of this study is to show the prevalence and distribution of hypertension according to the various kinds of biochemical parameters within the studied people. Materials and methods: Here a community-based survey work has been conducted using pre-structured questionnaire for identifying the prevalence and distribution of hypertension in relation to various kinds of factors like sociodemographics, anthropometric and biochemical parameters of blood and urine samples within the Scheduled Caste Community of three selected villages (viz. Chowgachha, Bagula and Priyanagar) of the District Nadia, West Bengal, India. The members of households, who were between 20-70 years of age, were interviewed and examined to collect the data regarding hypertension. Blood and urine samples were also collected by a registered medical practitioner from willing participants for the biochemical study. Data were analyzed using Chisquare test at both $5 \%$ and $1 \%$ levels of significance. Results: The biochemical study of blood showed that there was a significant increase of blood pressure with increasing blood glucose, total-cholesterol, triglyceride, LDL-C and $\mathrm{Na}^{+}$level. Although the optimal level of HDL-C and $\mathrm{K}^{+}$of blood showed the potency of blood pressure regulation. The people those who take additional dietary salt had the greater tendency of blood serum $\mathrm{Na}^{+}$as well as blood pressure. Conclusion: The results of this study clearly indicate that there was a significant role of hyperglycemia, dyslipidemia and high serum $\mathrm{Na}^{+}$level in the development of hypertension.

Keywords: Hypertension, Cardiovascular disease, Scheduled Caste Community, Hyperglycemia, Dyslipidemia.

## Introduction

Hypertension or abnormally high blood pressure is the leading cause of cardiovascular disease worldwide. It remains silent, being generally asymptomatic during its clinical course. As it is hidden beneath an outwardly asymptomatic appearance, the disease does immense harm to the body in the form of 'Target Organ' damage, hence, it is the 'Silent Killer' [1].
Hypertension and dyslipidemia are widely recognized risk factors for cardiovascular disease [2, 3]. Approximately $40 \%$ of the persons with essential hypertension also have hypercholesterolemia. Genetic studies have established a clear association between

[^0]hypertension and dyslipidemia [4].
Increasing age, body mass index, central obesity and impaired glucose tolerance/diabetes were associated with both hypertension and prehypertension in an affluent north Indian population. Hypertension and type 2 diabetes mellitus also tend to coexist. Hypertension is approximately twice as common in persons without diabetes, and the association is even stronger in African Americans and Mexican Americans. The leading cause of death in patients with type 2 diabetes is coronary heart disease, and diabetes increases the risk for acute myocardial infarction as much as a previous myocardial infarction in a nondiabetic person [5]. Hypertension, insulin resistance, dyslipidemia and obesity often occur concomitantly [6].There was a high prevalence of cardiovascular risk factors like central obesity, elevated LDL-cholesterol, abnormal glucose tolerance and smoking in the general population. Two or more of
these risk factors were present in a higher proportion of hypertensive and pre-hypertensive, compared to normotensive subjects [7]. Several epidemiological and clinical studies have demonstrated that a low or reduced intake of salt is associated with lower blood pressure [8]. The etiological studies investigating the relation between salt intake and stroke have generally produced positive associations [9, 10]. Studies in animals have shown that a high salt intake significantly increases renal excretion of water due to increased water intake [11-13]. When salt intake was increased there was an increase in plasma sodium and an increase in plasma osmolality, which is known to stimulate thirst and antidiuretic hormone secretion [14]. The biochemical factors which are associated with the development of hypertension within the Scheduled Caste community are not studied elsewhere. To save this community from the harmful effects of hypertension, we estimated the current prevalence and distribution of hypertension according to the different serum biochemical factors within this Scheduled Caste community of the District Nadia, West Bengal, India.

## MATERIALS AND METHODS

## Population based survey

A cross sectional door-to-door community based survey work was conducted to investigate the prevalence of usual salt-related hypertension within the SC community of three selected villages (viz. Chowgachha, Bagula and Priyanagar) of the district Nadia, West Bengal, India. About 2,453 members of households of study areas were interviewed and detailed information (i.e., age, sex, weight and height for BMI, waist and hip for WHR, HR, blood pressure, physical activity, oil intake, salt intake etc.) regarding hypertension were recorded. Average age of the studied individuals is approximately $41.58 \pm 14.25$ (range, 20-70 yrs). Data were collected from 10.00 am to 4.00 pm .

## Definition criteria and Blood pressure measurement

The seventh report of the Joint National Committee on Prevention, Detection, Evaluation and Treatment of High Blood Pressure (JNC-VII report) has recommended a new classification for adults-18 years or older: Normal: $<120 / 80 \mathrm{mmHg}$, pre-hypertensive: $120-139 / 80-90 \mathrm{mmHg}$ and hypertensive: >140/90 mmHg [15]. The blood pressure was measured by the authentic mercury and digital (HEM-7111 and HEM4030, Omron healthcare, Kyoto, Japan)
sphygmomanometer in supine position after taking rest at least for 10 minutes.

## Blood and urine biochemical analysis

The biochemical analysis of serum and urine was done in 114 people of the study areas. Out of 114 people, forty three (43) hypertensive and seventy one (71) were normotensive (NTN) people. The studied people took their usual diet and were instructed to collect 24 -hour urine sample for the measurement of volume and electrolytes $\left(\mathrm{Na}^{+}, \mathrm{K}^{+}\right.$and $\left.\mathrm{Cl}^{+}\right)$. Fasting blood sample was also collected for serum electrolytes $\left(\mathrm{Na}^{+}, \mathrm{K}^{+}\right.$and $\mathrm{Cl}^{+}$) and other biochemical analysis like blood sugar, $\mathrm{Hb} \%$ and lipid profile regarding hypertension.
The biochemical analysis was done by a semiautomatic biochemical analyzer (Prietest-easy lab, Robonik India Pvt. Ltd., Mumbai, India).

## Statistical analysis

Data were expressed as Mean $\pm$ SEM or SD, and were analyzed using Chi-square test at both $5 \%$ and $1 \%$ levels of significance. SPSS 12.0 software for windows was used to analyze the data.

## Results

The prevalence and distribution of hypertension according to different kinds of biochemical factors of blood and urine of willing candidates $(\mathrm{N}=114)$ during data collection regarding hypertension are depicted in the Table-1. The $26.31 \%$ of the total studied sample is known to be hypertension.
From the analyzed data it is found that hypertension is common in those groups who have higher level of blood glucose (blood glucose: $<100 \mathrm{mg} / \mathrm{dl}=20.68 \%$ and $\geq 100 \mathrm{mg} / \mathrm{dl}=44.44 \%$ ), total cholesterol (Total cholesterol: $<175 \mathrm{mg} / \mathrm{dl}=15.25 \%$ and $\geq 175 \mathrm{mg} / \mathrm{dl}=$ $38.18 \%$ ), Tg ( $\mathrm{Tg}:<100 \mathrm{mg} / \mathrm{dl}=10.81 \%$ and $\geq 100$ $\mathrm{mg} / \mathrm{dl}=33.76 \%$ ), LDL-C (LDL-C: $<100 \mathrm{mg} / \mathrm{dl}=$ $9.09 \%$ and $\geq 100 \mathrm{mg} / \mathrm{dl}=33.33 \%$ ), serum sodium ions $\left(\mathrm{Na}^{+}:<140 \mathrm{mmol} / \mathrm{L}=12.72 \%\right.$ and $\geq 140 \mathrm{mmol} / \mathrm{L}=$ $38.98 \%$ ) and urine potassium ions ( $\mathrm{K}^{+}:<75 \mathrm{mmol} / \mathrm{L}=$ $7.69 \%$ and $\geq 75 \mathrm{mmol} / \mathrm{L}=36 \%$ ) level whereas inverse relationship of hypertension occurs in blood HDL-C (HDL-C : $<40 \mathrm{mg} / \mathrm{dl}=39.62 \%$ and $\geq 40 \mathrm{mg} / \mathrm{dl}=$ $14.75 \%)$, urine $\mathrm{Na}^{+}\left(\mathrm{Na}^{+}:<100 \mathrm{mmol} / \mathrm{L}=44.44 \%\right.$ and $\geq 100 \mathrm{mmol} / \mathrm{L}=10 \%)$ and serum $\mathrm{K}^{+}\left(\mathrm{K}^{+}:\langle 4 \mathrm{mmol} / \mathrm{L}=\right.$ $48.07 \%$ and $\geq 4 \mathrm{mmol} / \mathrm{L}=8.06 \%$ ) groups. Hypertension is independent with the change of serum VLDL-C, serum $\mathrm{Cl}^{-}$and urine $\mathrm{Cl}^{-}$level.
The Chi-square test for the test of independence attribute reveals that hypertension is significant in the
group with higher level of blood glucose ( $\chi^{2}=7.716$, d.f. $=1, \mathrm{p}<0.05$ ), total cholesterol ( $\chi^{2}=5.99$, d.f. $=1$, $\mathrm{p}<0.01), \operatorname{Tg}\left(\chi^{2}=6.791\right.$, d.f. $\left.=1, \mathrm{p}<0.01\right)$ LDL-C $\left(\chi_{2}^{2}\right.$ $=7.106$, d.f. $=1, \mathrm{p}<0.05)$, serum sodium ions ( $\chi^{2}$ $=10.119$, d.f. $=1, \mathrm{p}<0.01)$ and urine potassium ions $\left(\chi^{2}\right.$ $=10.60$, d.f. $=1, \mathrm{p}<0.01$ ) levels whereas inverse relationship of hypertension occurs in blood HDL-C ( $\chi$
${ }^{2}=5.99$, d.f. $\left.=1, \mathrm{p}<0.01\right)$, urine $\mathrm{Na}^{+}\left(\chi^{2}=17.389\right.$, d.f. $=1$, $\mathrm{p}<0.05)$ and serum $\mathrm{K}^{+}\left(\chi^{2}=23.35\right.$, d.f. $=1, \mathrm{p}<0.001$ groups. Hypertension is independent with the change of serum VLDL-C ( $\chi^{2}=0.305$, d.f. $=1, \mathrm{p}>0.05$ ), serum $\mathrm{Cl}^{-}\left(\chi^{2}=5.99\right.$, d.f. $\left.=1, \mathrm{p}<0.05\right)$ and urine $\mathrm{Cl}^{-}\left(\chi^{2}\right.$ $=0.174$, d.f. $=1, \mathrm{p}>0.05$ ) levels.

## Discussion

Various biochemical factors which are associated for the development of hypertension have been studied in this investigation. The prevalence of hypertension in relation to serum fasting glucose level was increased in this study. The rate of hypertension in the studied people with $<100 \mathrm{mg} / \mathrm{dl}$ and $>100 \mathrm{mg} / \mathrm{dl}$ fasting blood glucose levels were $20.68 \%$ and $44.44 \%$ respectively. $\chi^{2}$-test showed the significant association between fasting blood sugar and hypertension. The prevalence of hypertension in patients with type 2 diabetes is up to three times greater than in age and gender matched non diabetic patients [16, 17].The patients with diabetes mellitus have a three to six fold increase in stroke risk, mostly attributable to hypertension, which occurs in $40 \%$ to $70 \%$ of this population. Tight blood pressure control significantly reduces stroke risk for these individuals [18].Incidence of hypertension was associated with dyslipidemia. The rate of hypertension was gradually increased with increase of serum total cholesterol, triglycerides and LDL-cholesterol levels. On the other hand, prevalence of hypertension was inversely associated with serum HDL-cholesterol level. Several studies were examined prospectively whether serum lipid levels (total-cholesterol, triglycerides, HDL-C and LDL-C) are associated with the subsequent development of hypertension in middle age adults. Higher levels of triglycerides [19-21], higher totalcholesterol 22, 23], and higher level of LDL-C [20, 24] were found to be associated with an increased risk of hypertension. In most studies, serum HDL-C levels showed an independent and inverse association with incident hypertension [19, 20, 22-24]. Both the systolic and diastolic blood pressure is positively correlated with high salt intake. Many other scientists were also worked on the development of salt-related blood pressure [25-28].High salt intake significantly increases renal excretion of water due to increased water intake. This compatible finding was also reported by some other researchers [12, 13, 29, 30]. The development of hypertension in some individuals of high salt intake group is mainly due to poor renal functional capacity to handle/excrete an excess renal volume (Uv) and renal salt or sodium (Us). This is also diagnosed by other workers [31, 32].

## Conclusion

From this study it can be concluded that the incidence of hypertension was gradually increased with increase of hyperglycemia, hyperlipidemia and higher salt intake within the Scheduled Caste Community of the District Nadia, West Bengal, India.

## Acknowledgements

The authors are grateful to the people of the Scheduled Caste Community of the District Nadia, West Bengal, India, those who provided whole-hearted support for the collection of data regarding hypertension during field study.
